That's how long it takes to fall two stories. That's how long it takes for life to change. When Michael Murphy was 21, he fell off a roof at college and landed flat on his back, severing his spine. They say that nobody understands their own traumatic injury just after it happens—but Michael did. Every person falls. They fall short in school, in life, in work, and in love. Their lives sometimes feel punctuated by those downfalls—the rejection letters, the unrequited love, the missed promotions, the life altering traumas. Everyone falls. But then what? *When I Fell* is a true tale of going from abled, to disabled, to empowered. It combines the story surrounding Michael's recovery with the science of resiliency and thriving—what psychologists are now calling Posttraumatic Growth (PTG)—to teach readers how to hit home runs when life throws them curves. Befitting new mainstream acceptance for disabilities, *When I Fell* is as much a memoir as it is a message. It features the five principles established by Drs. Tedeschi and Calhoun—the pioneers who coined the phrase in the 1990's—for scientific validation to bring PTG further into the public eye. *Physical Therapy Documentation* Peterson's Issue will cover: single muscle fiber electrophysiology, skinned muscle fibers, magnetic resonance imaging in muscular dystrophy, ultrasound of nerve and muscle, microgenomics of the motor neuron system, and electrodiagnostic studies in animal models.

Integrated Practice Elsevier Health Sciences

BackgroundPalliative care (PC) and best Supportive Care are complex areas to promote and advance. Many people need and benefit from them, therefore education, spreading knowledge and

existence of interdisciplinary teams (IDT) are required to ensure best quality of life. Nowadays only 15% of Countries have Hospice and Palliative Care (HPC) integrated inside their national health system. Among those countries, few offer physical therapies. Complementary and other non-pharmacological strategies used alongside traditional analgesic approach aims to help patients in maintaining and improving functionality in order to obtain at the same time psychological benefits. Physical therapies (PT) are part of a non-pharmacological approach, including several different techniques applied by physical therapists (PTs) with the purpose not only to manage the symptoms but also to improve Quality Of Life (QOL) of patients receiving pain rehabilitation and palliative care. It allows PTs to be part of an IDT and being active part of the holistic care of the patient. Aims: Linking PC with physical rehabilitation or physical exercise (PE), the aim was to critically evaluate the evidence for the effectiveness, benefits and weaknesses of PT (exercise) in end-of-life care. Due to the results obtained and the strength of the evidence, the author suggests a first protocol involving an IDT to best fit the evidence. Methods: A systematic review has been conducted, screening and reviewing the most recent studies published and related to this topic. More than 10 among databases and journals has been investigated to answer the aim. Results: Eight studies fitted for the analysis discussing the role of physical therapy intervention in palliative care setting. The quality of the studies was done following QASP/CASP checklists. Improvements ($p < 0.01$) were observed in physical performance, fatigue, and overall quality-of-life scores. A first physical exercise programme is suggested. Conclusions: An holistic biopsychosocial intervention (Total Pain concept) is the key for those people with complex and life-threatening illnesses. Not only for patients but also for the caregivers underlying the importance of a IDT. PTs play an important role inside a team focusing their intervention in improving functionality and QOL turning to physical and functional dimensions of care. Around 75% of the population will need PC therefore it is indispensable to start offering i) the best services, ii) where patients want, iii) taking the best decisions (right care, right place, right time). PT/PE plan has to be tailor-made and based on the general prospective evolution of the patient, in his capability to recover his functionality and his desire to take part to the rehabilitation programme. The use of simulated patients is a developing instructional strategy in physical therapy education (PTE) programs. However, it is unknown if using simulated patients during instruction yields better outcomes than the traditional use of peer role-play. This two-arm randomized, experimental design investigated the effect of type of simulation-based instruction, simulated patients compared to peer role-play, on clinical reasoning and confidence of students enrolled in an entry-level PTE program learning patient transfer skills. Upon the conclusion of two instructional sessions, clinical reasoning was measured by the Think Aloud Standardized Patient Examination (TASPE) during a simulation experience. Student confidence in performing future acute care skills was measured by the Acute Care Confidence Survey (ACCS) following the simulation experience. Two independent-samples t-test demonstrated that there was not a statistically significant difference in the students' TASPE scores or the ACCS scores based on the type of simulation-based instruction. This study provides evidence that peer role-play can be just as effective in improving physical therapist student clinical reasoning and confidence outcomes compared to using simulated patients when instructing patient transfer skills. Although the use of simulated patients may appear to promote deeper learning by portraying a more real scenario for practicing patient care skills, it is no more advantageous than peer role-play in terms of physical therapist students' clinical reasoning and confidence skills when learning patient transfer skills.

The procedure of skin grafting has been performed since 3000BC and with the aid of modern technology has evolved through the years. While the development of new techniques and devices has significantly improved the functional as well as the aesthetic results from skin grafting, the fundamentals of skin grafting have remained the same, a healthy vascular granulating wound bed free of infection. Adherence to the recipient bed is the most important factor in skin graft survival and research continues introducing new techniques that promote this process. Biological and synthetic skin substitutes have also provided better treatment options as well as HLA tissue typing and the use of growth factors. Even today, skin grafts remain the most common and least invasive procedure for the closure of soft tissue defects but the quest for perfection continues.
